

NATIONAL OBSERVATORY OF ATHENS

No. 3

**SEISMOLOGICAL INSTITUTE**  
**BULLETIN**  
**1952**

ATHENS 1953

## INTRODUCTION

The geographic coordinates of the seismographic station are:  $37^{\circ}58'22''$  N and  $23^{\circ}43'10''$  E. The instruments are standing 95 m. above mean-sea-level on a subsoil consisting of calcite tuff.

The Instruments are a set of seismographs with mechanical recording according to Wiechert.

One astatic horizontal seismograph,  $M = 1000$  kg.

One vertical Seismograph,  $M = 1300$  kg.

The mean values of the natural period of the undamped pendulum  $T$ , of the damping ratio  $\epsilon$  and of the static Magnification  $V$  are for the year 1952:

Instruments	$T_0$	$\epsilon$	$V$
Wiechert (NS Comp.)	7.2	4.1	160
" (EW Comp.)	7.5	4.5	168
" (Z Comp.)	1.6	1.6	276

The velocity of the recording paper is about 30 mm per minute.

The time is Greenwich mean time, from midnight till midnight.

Symbols and Abbreviations are the very known.

The distance of epicenter of the shallow shocks has been

calculated by means of curves on the time tables of Jeffreys and Bullen (1948), and that of deep shocks by means of the "Chart of Depth, Time and distance for deep-focus Earthquakes" by G.J. Brunner, S.J. Saint Louis University 1935. The travel time curves of near earthquakes after J.H. Hodgson (1945) were proved more satisfactory for the calculation of the  $\Delta$  - distance of near normal shocks.

The maximal amplitudes measured from the medium line have been calculated in cases of strong short-distance shocks by means of the formula:

$$W = \frac{V}{\sqrt{\left[1 - \left(\frac{T}{T_c}\right)^2\right]^2 + 4 \left(\frac{T_0}{2\pi}\right)^2 \left(\frac{T}{T_0}\right)^2}}$$

The amplitudes have been omitted when the oscillations were too irregular.

The first part of the Bulletin contains readings of main impulses of distant shocks. Additional readings are given when possible. Data under heading remarks refer to the locations after USCGS and BCIS and in some cases according to JSA or ING. The magnitude is given ordinarily according to Pasadena and Strasbourg. Readings of local and short distance shocks are given separately in the second part. The third section contains shocks felt in the Greek area which have not been recorded, and a table with the intensities of the shocks felt in Greece.

On the annexed map are plotted the epicenters of near shocks located by BCIS and the corresponding area of highest intensity according to the reports of felt shaking. Intensities are given on Mercalli-Sieberg scale. In case of two near

epicenters the strongly shaken area of the stronger earthquake and the region of the reported highest intensity of the less important shock are given. Epicenters marked in by + denote an initial compression at Athens and by - an initial dilatation. In doubtful cases the symbols of the epicenters are not marked. Epicenters of probably deep shocks are marked by a triangle circumscribed. The date of the shocks is noted close to the symbols of the epicenters. The arabic numerals indicate the magnitude of the shocks derived to the nearest quarter by means of the formula:

$$M = 0.20 \Delta + 0.67 \log a + 3.80$$

hold in Japan. In lack of maximum amplitude of the horizontal ground motion in Athens the magnitude was arbitrarily estimated from the distances out to which the direct waves were recorded, as entered in the Bulletin of the BCIS.

Athens, July 25, 1953.

Prof. Dr. A. GALANOPOULOS.
